Converts sphinx and breathe inventory files to doxygen tag files.

CHAPTER 1

Introduction

`xhale` transforms an inventory file given by sphinx into a doxygen tag file. This package is mainly used for `xeus-cling` in order to be able to get the documentation of a C++ package in a jupyter notebook.

To create your tag file, you just have to use the script `xhale` and give the following arguments

- the package name which will be the name of the tag file
- the url where to find the inventory file

Here is an example

```
xhale -p xtensor --url https://xtensor.readthedocs.io/en/latest/
```

1.1 xhale package

`xhale.xhale.extract_tag`(*inventory*, *url*)
extract data from sphinx inventory.

The extracted datas come from a C++ project documented using Breathe. The structure of the inventory is a dictionary with the following keys

- cpp:class (class names)
- cpp:function (functions or class methods)
- cpp:type (type names)

each value of this dictionary is again a dictionary with

- key : the name of the element
- value : a tuple where the third index is the url to the corresponding documentation

Parameters

- `inventory` (*dict*) – sphinx inventory

- **url** (*url of the documentation*) –

Returns

- *dictionary with keys class, class_methods, func, type*
- *but now the class methods are with their class.*

`xhale.xhale.get_sphinx_inventory(url)`

get the sphinx inventory from a url.

Parameters **url** (*url of the package where find objects.inv file*) –

Returns the inventory

Return type dict

`xhale.xhale.write_tagfile(tag_elem, package, url)`

write the doxygen tagfile (package.tag).

Parameters

- **tag_elem** (*dictionary given by extract_tag*) –
- **package** (*name of the package*) –
- **url** (*url of the documentation*) –
